Received 8 September 1998/Returned for modification 4 November 1998/Accepted 19 January 1999

In a search for new anti-autoimmune agents that selectively suppress activation of autoreactive T cells, one such agent, 5-methyl-3-(1-methylethoxy)benzo[b]thiophene-2-carboxamide (CI-959-A), was found to be effective. This compound, which is known to suppress tumor necrosis factor alpha (TNF-α)-induced CD54 expression, inhibited the primary proliferative response of the T cell to antigen (Ag)-presenting cells (APCs) including allogenic dendritic cells (DCs), autologous Epstein-Barr virus-infected B cells, and human T lymphotropic virus type I (HTLV-I)-infected T cells. Autoreactive T cells from patients with HTLV-I-associated myelopathy/tropical spinal paraparesis (HAM/TSP) spontaneously proliferate in vitro, and their activation is reported to be associated with CD54 expression. The spontaneous proliferation of T cells from patients with HAM/TSP was entirely blocked by CI-959-A. However, in this study, the T-cell proliferation in 15 patients with HAM/TSP was found to depend more extensively on major histocompatibility complex (MHC) class II and CD86 than on CD54 Ags. Since most important APCs for the development of HAM/TSP are DCs and HTLV-I-infected T cells, the effect of CI-959-A on DC generation and on the expression of surface molecules on activated T cells is examined. CI-959-A suppressed recombinant granulocyte-macrophage colony stimulating factor (GM-CSF)- and recombinant interleukin-4-dependent differentiation of DCs from monocytes and inhibited the expression of CD54 and, more extensively, MHC class II and CD86 Ags. CI-959-A showed little toxicity toward lymphoma or HTLV-I-infected T-cell lines or toward monocytes and cultured DCs. These results suggest that CI-959-A might be a potent anti-HAM/TSP agent.

Human T lymphotropic virus type I (HTLV-I)-associated myelopathy/tropical spinal paraparesis (HAM/TSP) is thought to be an autoimmune disease induced by HTLV-I infection (8, 9, 24). The T lymphocytes obtained from patients with HAM/TSP patients produce interleukin-2 (IL-2) in vivo and proliferate spontaneously in vitro without any additional stimuli or cytokines (35). This spontaneous proliferation of T lymphocytes (SPL) depends on the interaction of T cells with antigen (Ag)-presenting cells (APCs) such as dendritic cells (DCs) (17, 25) and HTLV-I-infected CD4+ T cells (15, 32). The DCs localized in the blood and nonlymphoid organs are considered to be functionally immature, in that they are optimized for the uptake and processing of Ag but not for the initiation of primary T-cell responses. However, after the uptake of Ag and exposure to inflammatory agents including tumor necrosis factor alpha (TNF-α) and IL-1, the DCs undergo a process of maturation and gain the ability to present Ag to T cells for their priming (22, 26). In addition to DCs, HTLV-I-infected CD4+ T cells directly stimulate autologous CD4+ T cells in a major histocompatibility complex (MHC) class II- and CD86 molecule-dependent fashion (32). Among the T cells stimulated with these APCs, some might cross-react with self Ags and closely associate with the development of HAM/TSP.

We have been searching for compounds that inhibit the cellular interaction between APCs and T cells to suppress the activation of autoreactive and Ag-specific T cells. The molecules associated with the APC-T-cell interaction may provide an effective target for therapy for autoimmune diseases. Binding of APCs and T cells is initiated by contact of adhesion molecules, such as CD54 and CD11a/CD18, expressed on both cells, and induction of sustained proliferation of T cells requires two independent signals provided by APCs: a T-cell receptor-mediated Ag-specific signal and a signal mediated by costimulatory molecules (CSMs) (10, 20) including CD86 and CD80 Ags (1, 11, 31). Blocking of their tight binding through adhesion molecules or interaction of the CSMs with CSM ligands effectively suppressed the abnormal expansion of disease-associated T cells in vivo and in vitro (19, 30, 32) and sometimes effectively induced a long-term unresponsiveness of T cells to recall stimuli.

5-Methyl-3-(1-methylethoxy)benzo[b]thiophene-2-carboxamide (CI-959-A) is known to inhibit CD54 expression, and its derivative is reported to inhibit casein kinase II (4). In the present study, we found that CI-959-A markedly suppressed SPL in patients with HAM/TSP. Furthermore, the compound suppressed the primary T-cell proliferative response to stimuli provided by various APCs, the differentiation of immature DCs from monocytes and their subsequent maturation, and the induction of expression of MHC class II, CD54, and CD86 Ags on activated CD4+ T cells.

MATERIALS AND METHODS
Preparation of responder cells and stimulators. Peripheral blood mononuclear cells (PBMCs) were donated, with informed consent, by 15 patients diag-

*The EC_{50} of CI-959 and CI-959-A were determined by quantification of the inhibition of the proliferative response of T cells to various stimulators. The proliferation of unseparated PBMCs (5 × 10^5 cells/well) was indicated by the uptake of 1,500 cpm; therefore, uptake of more than 4,000 cpm was considered a positive response. The optimal concentrations of the compounds were determined in advance. The proliferative response of unseparated PBMCs (5 × 10^5 cells/well) in the absence of compounds was 156,274 ± 112,391 cpm for PHA (0.2 μg/ml), 11,937 ± 3,514 cpm for CI-959, and 14,771 ± 10,026 cpm for CI-959-A (5 × 10^5 cells/well). The values are means ± standard deviations for three to six independent donors.

duced with HAM/TSP at the Kagoshima University Hospital and by 8 healthy donors. The disease was diagnosed according to the World Health Organization criteria for HAM/TSP. The age range of the patients was 39 to 75 years, and the range of years with disease was 4 to 37. The patient population comprised 10 females and 5 males, and the severity of disease was scored as 0 to 7 by motor disability grading (22). No patient was coinfected with human immunodeficiency virus type 1. The PBMCs were isolated from heparinized blood by using Ficoll-Paque Plus (Pharmacia, Uppsala, Sweden) and were cryopreserved in liquid nitrogen as described previously (12). The HTLV-I-infected cell lines (HT-1, HT-2, and HT-3) were established by cocultivation of CD4+ T cells from healthy donors with a mitomycin C-treated HTLV-I-producing cell line, MT-2, which was provided from 3 days after culture and reached a maximum at day 6. The uptake of 112,391 cpm for PHA (2 μg/ml), 10,026 cpm for allogeneic PBMCs (5 × 10^5 cells/well), 14,771 ± 10,026 cpm for allogeneic cultured DCs (5 × 10^5 cells/well), 28,165 ± 11,205 cpm for autologous EBV-infected B cells (3 × 10^5 cells/well), and 30,306 ± 19,772 cpm for autologous HTLV-I-infected T cells (5 × 10^5 cells/well). Values are means ± standard deviations for three to six independent donors.

ters and CD86 were determined in advance. The proliferative response of unseparated PBMCs (5 × 10^5 cells/well) was indicated by the uptake of 1,500 cpm; therefore, uptake of more than 4,000 cpm was considered a positive response. Suppression of SPL in patients with HAM/TSP by CI-959-A.

We obtained PBMCs from 15 patients with HAM/TSP and individually determined the therapeutic effect of CI-959-A on them (Fig. 1). To this end, we induced SPL in the presence of the compounds and found that 1 μM CI-959-A inhibited the T-cell proliferation by 83.1%, on average, in patients with HAM/TSP, whereas CI-959 suppressed T-cell proliferation by less than 18% (P < 0.001) (Fig. 1). SPL suppression by CI-959-A was constantly observed in most patients examined. In order to make sure that SPL is induced by contact of T cells with APCs mainly through CD54 Ag, we determined the molecules that are chiefly associated with SPL induction. The MAb to MHC class I Ags mildly affected the suppression of SPL (36.6% suppression), and the MHC class II MAb was markedly effective in the suppression of SPL (74.4%). Of the various MAbs to CSMs (CSMs CD40L, CD80, CD54, CD58, CD86), the MAb to CD54 Ag was most effective.

*The 50% inhibitory concentrations (IC50s) of CI-959 and CI-959-A were determined by quantification of the inhibition of proliferation of HTLV-I-infected CD4+ cell lines and T-cell lymphoma lines. The proliferation of cell lines cultured for 4 days in the absence of compounds was 6,728 ± 512 cpm for HT-1 (2 × 10⁴/well), 1,304 ± 1,859 cpm for HT-2 (2 × 10⁴/well), 7,135 ± 990 cpm for HT-3 (2 × 10⁴/well), 14,541 ± 7,618 cpm for Jurkat (2 × 10⁴/well), 10,990 ± 4,619 cpm for CCRF-CEM (2 × 10⁴/well), and 19,185 ± 8,003 cpm for MOLT-4 (2 × 10⁴/well). Values are means ± standard deviations for three separate experiments.

FIG. 1. Inhibitory effects of CI-959-A and MAbs to CSMs on SPL for patients with HAM/TSP. PBMCs were donated by 15 patients with HAM/TSP, and 7.5 × 10⁴ cells were cultured for 6 days in the presence of 10 μg of MAbs per ml or a 1-μM concentration of compound. The proliferation of T cells in the absence of test materials was 14,314 ± 7,255 cpm (mean ± standard deviation for 15 individuals; the individual titers were as follows: 27,368, 8,512, 8,585, 10,864, 4,154, 24,777, 11,593, 15,348, 10,636, 16,215, 10,723, 25,308, 5,256, 20,074, and 15,301 cpm). A mixture of normal mouse IgG subclasses (IgG1, Ig2a, Ig2b, and Ig3) was used as control antibody. * P < 0.001. The inset shows a dose-response curve for CI-959-A on SPL for patients with HAM/TSP. Data for three representative patients were used, and [³H]thymidine uptake by T cells without the compound was determined to be 100%. The mean ± standard deviation for three patients is shown.
and CD86), the MAb to CD86 was the most effective (80.1%), and the MAb to CD58 showed moderate inhibition of SPL (55.4%). However, in contrast to previous reports (13, 36), the MAb to CD54 suppressed SPL by only 19.6%. These findings were further confirmed by combination treatment. All the combinations of MAbs (MAbs to CD54 plus CD58, CD54 plus CD86, and CD58 plus CD86) achieved more than 60% inhibition, and the combination of MAbs to CD58 and CD86 was the most effective (88.4%). However, no additive suppressive effects of the MAb to CD54 to the suppressive effect of the MAb to CD58 or CD86 were observed. The other two MAbs (MAbs to CD40L and CD80) had minimal effects. T cells have been reported to express the CTLA-4 Ag on the cell surface after activation. However, neither CD4+ T cells nor CD8+ T cells expressed the CTLA-4 Ag before or after in vitro induction of SPL. These results suggest that SPL is induced by the interaction with APCs and that it depends largely on the MHC class II, CD86, and CD58 molecules expressed on the APCs.

Suppression of DC generation and CSM expression on CD4+ T cells by CI-959-A. In order to clarify a mechanism of CI-959-A on SPL suppression in patients with HAM/TSP, we examined the effects of the compound on APCs, among which the most important are DCs and HTLV-I-infected CD4+ T cells (15, 17, 25, 32). CI-959-A suppressed the differentiation of DCs from normal monocytes (Table 3). The PBMCs donated by healthy individuals and plastic-adherent monocytes were cultured in the presence of rGM-CSF and rIL-4 for 7 to 10 days to induce DCs. The DCs that express CD83 at low levels and CD86 at moderate levels (termed CD83+DCs) differentiated in the presence of the cytokines, and DCs that were CD83 positive and that expressed the CD86 Ag at high levels (CD83+DCs) differentiated following the addition of TNF-α. The rates of production of CD83+DCs and CD83+DCs were 7.3 and 2.7%, respectively. CI-959-A at 1 μM suppressed the differentiation of both types of DCs by more than 50%. There was a statistical difference in the DC differentiation rate between CI-959-A and CI-959. However, the DCs that differentiated in the presence of CI-959-A expressed MHC class II and CD54, CD58, CD1a, and CD86 molecules to the same extent as those that differentiated in the absence of the compound or in the presence of control compound, although their differentiation rates were reduced. The mean fluorescence intensity for those Ags on DCs generated with CI-959-A was minimally reduced compared to that for the other two DCs (Fig. 2). The inefficient generation of DCs was supported by the functional evidence (Fig. 3). CD83+DCs differentiated from various numbers of PBMCs in the presence of CI-959-A at 1 μM in 96-well flat-bottom culture plates. After 10 days of culture, the APC activity of the DCs was assessed by allogeneic MLR. The DCs that had differentiated in the presence of 1 μM CI-959-A stimulated the allogeneic responder cells less efficiently than those which had differentiated normally, and the difference was

*The effect of CI-959-A on differentiation of DCs from PBMCs was determined. CD83+DCs were differentiated by culturing PBMCs in the presence of GM-CSF and IL-4 for 7 days, and CD83+DCs were differentiated by using GM-CSF, IL-4, and TNF-α. In each experiment, five independent cultures were used. The DC differentiation rate was calculated as follows: 100 × (number of DCs differentiated/number of PBMCs used). Means ± standard deviations are shown. 

a P < 0.05 compared with no compound.

b ND, not determined.
c P < 0.01 compared with no compound.
d P < 0.05 compared with CI-959.

e P < 0.05 compared with CI-959-A.

![FIG. 2. Expression of various molecules on DCs differentiated in the presence of CI-959-A. DCs were differentiated by using rGM-CSF (1000 U/μl) and rIL-4 (200 U/μl) for 5 days in the presence of CI-959-A (1 μM) or CI-959 (1 μM). The DCs were gated and examined for expression of HLA-DR, CD86, CD58, CD54, and CD1a. ---, control MAb; — — — , the indicated MAb. of PBMCs were cultured in a 96-well plate in the presence of 1 μM mitomycin C, washed, and used for T-cell stimulation. Allogeneic, unseparated PBMCs (5 × 10^6/well) were used as responders. Data represent those from three separate experiments.

FIG. 3. Inhibition of functional DC production by CI-959-A. Various numbers of PBMCs were cultured in a 96-well plate in the presence of 1 μM CI-959-A or CI-959 to produce mature DCs. After 7 days, the DCs were treated with mitomycin C, washed, and used for T-cell stimulation. Allogeneic, unseparated PBMCs (5 × 10^6/well) were used as responders. Data represent those from three separate experiments.

statistically significant. These results suggested that CI-959-A suppressed the generation efficiency of functionally competent DCs.

Furthermore, PBMCs donated by three healthy donors were stimulated with PHA (2 μg/ml) (Fig. 4). Seven days later, CD4^+ T cells expressed HLA-DR, CD54, CD58, and CD86 Ags. However, the surface expression of these Ags except for that of the CD58 Ag on the CD4^+ T cells activated in the presence of 1 μM CI-959-A was substantially suppressed. The production of cells expressing HLA-DR and CD86 Ags was most strikingly reduced, and expression of CD54 was moderately reduced by CI-959-A. In contrast to these Ags, the molecules constitutively expressed on CD4^+ T cells, such as CD28 and CD2, were not affected by CI-959-A. A control compound, CI-959, caused no suppression of Ag expression.

**DISCUSSION**

Although HAM/TSP is induced by infection with HTLV-I, it is categorized as an autoimmune disease (8, 9, 24), in that disease development is closely associated with the activation of CD4^+ and CD8^+ T cells which recognize HTLV-I gene products (6) and which may also cross-recognize neural Ags (21). We have been searching for compounds capable of suppressing the APC-dependent activation of autoreactive T cells. In such processes, we focused on a benzothiophene derivative, CI-959-A, since the compound has been shown to suppress TNF-α-induced expression of CD54 and CD62E molecules on nonprofessional APCs such as human umbilical vein endothelial cells (3). Actually, CI-959-A entirely blocked the interaction of T cells with various APCs including DCs, EBV-infected B cells, and HTLV-I-infected CD4^+ T cells (Table 1), probably through the suppression of expression of adhesion molecule CD54. In previous reports, CD54 and CD58 molecules were associated with the activation of T cells in patients with HAM/TSP (13, 36). This information prompted us to examine whether CI-959-A could inhibit the disease-associated activation of T cells in patients with HAM/TSP. The production of autoreactive T cells in patients with HAM/TSP is reflected in the extension of the in vitro SPL, and we found that the compound certainly suppressed the SPL in most of 15 patients with HAM/TSP. In contrast to previous reports, however, the SPL induction in the 15 patients examined in this study was found to be largely dependent on MHC class II, CD86, and CD58 molecules but not on CD54 molecules (Fig. 1). Thus, the suppression of SPL by CI-959-A seemed to be independent of its inhibition of CD54 expression. Then we determined the effect of the compound on the HAM/TSP-associated APCs, the most important of which are DCs (17, 35) and HTLV-I-immortalized CD4^+ T cells (15, 32). While CI-959-A exhibited little toxicity against nonproliferating DCs and their precursor monocytes and proliferating lymphocytes such as HTLV-I-infected T cells and T-cell lymphoma lines (Table 2) at the dose that suppressed T-cell proliferative responses to antigenic stimuli, this compound inhibited the differentiation of DCs from peripheral monocytes and the induction of expression of MHC class II, adhesion, and costimulatory molecules on activated CD4^+ T cells (Fig. 2 and 4). In addition to the fact that CI-959-A suppressed CD54 Ag expression on PHA-activated CD4^+ T cells, it more strongly affected the expression of HLA-DR and CD86 Ags. Therefore, the suppression of SPL in patients with HAM/TSP by CI-959-A might be more closely associated with its pharmacological action on disease-associated APCs.

The MAbs to CD80 or CD86 are shown to be effective in the prevention of autoimmune diseases in vivo in animal models of disease such as experimental autoimmune encephalomyelitis (14) and nonobese diabetes observed in NOD mice (16). There are also several human autoimmune diseases including rheumatoid arthritis in which DCs, CSMs, and autoreactive T cells play major roles in the induction and progression of disease (5, 33, 34). The culture of peripheral monocytes in the presence of rGM-CSF and rIL-4 in a directed differentiation into DCs (27, 29) that bear the phenotypic and functional characteristics of immature DCs (28, 29). Upon exposure to inflammatory cytokines, these cells undergo a maturation step and express CD83 Ag (2, 23, 26, 37). The fact that CI-959-A inhibited the differentiation of the immature type of DCs (CD83^-DCs) as well as the mature type of DCs (CD83^+ DCs) suggests that it suppresses both the uptake of Ag by CD83^-DCs and the presentation of Ag to naïve T cells by CD83^+ DCs. Furthermore, while CI-959-A affected the induction of MHC class II and CD86 molecules, it had no effect on the constitutively expressed molecules including CD28 and CD2 (Fig. 4). This may suggest that this compound is most effective at the phase of induction and rapid progression of diseases.

A derivative of CI-959-A, termed PD144795, is reported to inhibit casein kinase II (4) and quite recently has been reported to inhibit calcineurin (7). Although these pharmacological effects are associated with the transcriptional inhibition of human immunodeficiency virus type 1 and the blocking of transactivation of the human immunodeficiency virus type 1 long-term repeat, the relationship between those effects and the suppression of CSM expression and DC generation by CI-959-A has not been uncovered. Furthermore, it is not yet clear whether CI-959-A could similarly suppress casein kinase II and calcineurin. In terms of the chemotherapy and prophylaxis of autoimmune diseases such as HAM/TSP, CI-959-A
seems to be a potent drug candidate that should be further pursued.

ACKNOWLEDGMENTS

This work was supported in part by a Grant-in-Aid for a Second-Term Comprehensive 10-year Strategy for Cancer Control from the Ministry of Health and Welfare of Japan.
