ABSTRACT

Human papilloma virus (HPV) is able to inhibit the secretion of IFN-γ and the expression of some immune innate cell receptors. Immunoglobulin-like transcript-2 (ILT2) is a regulatory receptor that seems to participate in the pathogenesis of viral infections. We have studied the expression and function of ILT2 and the expression of other NK cell receptors in 23 healthy women before and after immunization with the HPV vaccine Gardasil. Receptor expression was analyzed by flow cytometry in freshly isolated peripheral blood mononuclear cells as well as after in vitro stimulation with Gardasil vaccine. In addition, the regulatory function of ILT2 on cell proliferation and IFN-γ production was analyzed. We found a significant increase in the expression of ILT2 by NK and CD3+CD56+ lymphocytes and monocytes after Gardasil immunization. In addition, the in vitro stimulation with Gardasil also increased the proportion of CD3-CD56+ILT2+ NK cells. Although the inhibitory function of ILT2 on cell proliferation was enhanced after HPV immunization, the in vitro engagement of this receptor did not affect the synthesis of IFN-γ induced by HPV. Finally, a significant increase in the expression of NKG2D, NKp30 and NKp46 by NK and CD3+CD56+ lymphocytes was detected after Gardasil immunization. Our data indicate that HPV immunization is associated with significant changes in the expression and function of different innate immune receptors, including ILT2, which may participate in the protective effect of HPV vaccines.
INTRODUCTION

Cervical cancer is the second cause of women mortality in the world, and 98% of these cases are associated to infection by human papillomavirus (HPV) [4]. HPV infection prevalence is reported between 2 to 44% worldwide, but this percentage is increased up to 70% in sexually active women. However, only 10 to 25% of infected women develop cervical lesions induced by HPV. In this regard, 90% of the women that acquire the HPV will eliminate the virus in less than 3 years [23].

The immune response elicited by HPV includes the production of specific antibodies as well as a cell mediated response, with activation of Th1 lymphocytes [20]. The humoral immune response is observed in approximately 50% of infected women, and only 20-25% of them will have significant antibody titers 10 years after the infection. On the other hand, the cellular immune response includes the activation of CD4+ Th1 cells, CD8+ cytotoxic lymphocytes and the synthesis and release of pro-inflammatory cytokines such as IL-12, IFN-γ, and TNF-α [20,6]. In this regard, it has been reported that L1 and L2 capsid viral proteins are immunogenic and it is widely recognized that immunization with these antigens confers effective protection against HPV infection [24]. However, HPV has different immune evasion mechanisms including its non-lytic effect and its episomal state in the initial period of the infection [28,11]. In addition, HPV is able to decrease the secretion of the chemokine IL-8 as well as to diminish the synthesis of IFN-γ [12]. Furthermore, it has been described that HPV infection is associated with a reduction in the expression of different innate immune receptors, including TLR9 [9], NKp30, NKp46 and NKG2D, diminishing the cytotoxic activity NK cells [7,2]. Finally, HPV is also able to inhibit the expression of the ζ chain of T cell receptor complex (CD247), and to induce the release of IL-10, interfering with the activation of Th1 lymphocytes [27,26].

Immunoglobulin-like transcript-2 (ILT2 or LILRB1/LIR1/CD85j) is a negative regulatory receptor expressed by different leukocyte subsets [16]. This receptor binds to different HLA class I molecules and the human cytomegalovirus (HCMV)
UL18 protein [17,1]. ILT2 has a close relationship with the killer inhibitory receptors (KIR), and exhibits cytoplasmic immunoreceptor tyrosine-based inhibitory motifs, which are able to recruit the SHP-2 phosphatase, inhibiting thus T cell activation [19]. ILT2 is expressed by myeloid cells, mainly phagocytic and antigen-presenting cells (monocytes, B lymphocytes, dendritic cells and macrophages). This receptor is also detected in a significant fraction of NK cells, and 4 to 20% of T lymphocytes, mainly CD8+ cells [14].

Different studies have shown that the expression and function of ILT2 is increased in HCMV infection, a phenomenon that could contribute to the pathogenesis of disorders caused by this virus [8,15]. In addition, it has been reported that ILT2 may also participate in the pathogenesis of HIV infection, tuberculosis, and some malignant conditions [13]. However, the possible role of this receptor in HPV infection has not been described.

In this work, we analyzed different immune parameters in healthy volunteers before and after immunization with the quadrivalent vaccine Gardasil. Thus, we have analyzed the expression and function of ILT2 as well as the expression of other NK cell receptors (NKG2A, NKG2D, NKp30 and NKp46) which seem to participate in the innate immune response against different viruses [8,15]. We have found that HPV immunization is associated with significant changes in the expression and function of ILT2, the number of IFN-γ producing cells and an increase in the expression of activation receptors by NK and CD3+CD56+ cells.
MATERIAL AND METHODS:

Patients and Samples. Twenty-three healthy volunteers were included in the study. All individuals were female, their age ranged from 14 to 34 years (mean = 25.8) and no evidence of HPV infection was detected in any of them. Immunization against HPV with the quadrivalent vaccine Gardasil was performed according to the manufacturer’s instructions. No side-effects of immunization were registered in any case. Informed consent was obtained in writing from all volunteers and this study was done in accordance with the principles set out in the declaration of Helsinki.

Peripheral blood samples were obtained before immunization (first sample, T0) and fifteen days after the administration of the first and third doses of Gardasil vaccine (days 15 and 195, T1 and T2 samples).

Cells. Peripheral blood mononuclear cells (PBMCs) were isolated by Ficoll-Hypaque (Sigma Chemical Co. St. Louis, MO) gradient centrifugation. Cells were suspended in RPMI 1640 culture medium (HyClone, Logan, UT), supplemented with 10% of fetal bovine serum (HyClone), 2.0 mM of glutamine, 100 UI/ml of penicillin and 100 μg/ml of streptomycin (Sigma).

Antibodies. The following monoclonal antibodies (mAb) were employed: anti-CD4, anti-CD8, anti-CD19, anti-CD56, and anti-CD14, all conjugated with phycoerythrin (PE) (eBioscience, San Diego, CA). An anti-CD3-PerCP mAb was purchased from BD Biosciences (San Jose, CA), and the ILT2 receptor was analyzed with a biotynilated mAb (R&D Systems, Minneapolis) and streptavidin conjugated with FITC (Sigma). For the analysis of expression of NK cells receptors, anti-CD3-PerCP, anti-CD56-APC, and anti-NKG2A, anti-NKG2D, anti-NKp30 and anti-NKp46 labeled with PE were employed (R&D).

Flow Cytometry Analysis: Cells were first immunostained with the biotynilated anti-ILT2 mAb, followed by incubation with streptavidin-FITC. Then, the
cells were incubated with the indicated antibody for 20 minutes at 4°C in dark conditions. Cells were analyzed in a FACSCalibur flow cytometer (Becton Dickinson, San Jose, CA), using the CellQuest software (Becton Dickinson).

For the analysis of the NK cell repertoire receptors, three-color flow cytometry analysis was performed by labeling with the anti-CD56-APC and anti-CD3-PerCp mAb. Then, samples were washed and incubated with the anti-NKp30, anti-NKp46, anti-NKG2A and anti-NKG2D labeled with PE. Finally cells were washed with PBS with 2% of fetal bovine serum and fixed in 1% of paraformaldehyde. Cells were analyzed in a FACSARia flow cytometer (Becton-Dickinson), using the FACSDiva software (Becton-Dickinson).

Inhibition of cell proliferation assays. PBMCs (1 x 10^6) were loaded with 0.5 mM of carboxyfluorescein succinimidyl ester (CFSE) and incubated during 72 or 96 hrs in standard conditions (with 5% of CO₂, 37°C, and 100% humidity) in the presence and absence of a mixture of anti-CD3 and anti-CD28 mAb (10 µg/ml, Immunotech, Marseille, France), and with the addition or not of 2 µg/ml of an agonistic anti-ILT2 mAb (HP-F1, BioLegend, San Diego, CA) plus a cross-linker antibody (4.0 µg/ml rabbit anti-mouse IgG, Sigma-Aldrich). After incubation, cells were washed and the proportion of divided cells (cells in which the CFSE was diluted during mitosis, and that show a diminished fluorescence emission) was determined by flow cytometry analysis (FACSCalibur flow cytometer). Results were expressed as the percent of divided cells.

Cell cycle analysis. Cell cycle analysis was performed by a DNA content assay by using propidium iodide staining and flow cytometry. PBMCs (1x10^6 poured in 48-well flat bottom plates) were cultured for the indicated times in the presence of Gardasil vaccine at the following concentrations of L1 protein: 10 ng/ml of HPV-6 and -18, and 20 ng/ml of HPV-11 and -16 or 20 ng/ml of HPV-6 and -18, and 40 ng/ml of HPV-11 and -16. Then, cells were harvested and incubated with a staining buffer (30 mg/ml propidium iodide, 0.5 mg/ml RNAse, and 1.0% Triton x-100, all from Sigma-Aldrich), for 30 min at 4 °C, and analyzed in a
FACSCalibur flow cytometer. Results were expressed as the percent of cell nuclei in the S, G2 and M phases of cell cycle.

**Cytokine Production Assays.** Supernatants from the different culture conditions were collected and the concentrations of the indicated cytokines were determined by ELISA (BD OptEIA, BD Biosciencies-PharMingen, San Jose, CA), according to the manufacturer’s instructions.

For the ELISPOT assay, PBMCs (2x10^5) were stimulated with the Gardasil vaccine and cultured for 48 hrs in the presence and absence of the HP-F1 anti-ILT2 mAb plus a cross-linker antibody. Then, the number of IFN-γ producing cells was determined by using a Mabtech ELISPot kit (Stockholm, Sweden) according to manufacturer’s recommendations. Finally the plates were read in a StereoZoom SZ-4 stereomicroscope (Leica, Wetzlar, Germany) with a 30x objective.

**Statistical Analysis:**

Results are represented as the arithmetic mean ± SD. Statistical analysis was made as indicated in each figure legend. A p value <0.05 was considered as significant. The statistical analysis was performed using the GraphPad Prism 4.0 software or the GraphPad InStat 3 (GraphPad Software, San Diego, CA).
RESULTS

Expression of immune innate receptors by PBMCs. We first explored the expression of ILT2 by different leukocyte subsets before and after Gardasil immunization, and stimulated in vitro or not with VLPs from this vaccine. We found that the expression of ILT2 (percentage of positive cells) by CD8+ cells diminished after Gardasil immunization (p<0.01, Fig. 1A and B, filled bars). In contrast, the expression of this regulatory receptor by NK (CD3-CD56+), NKT (CD3+CD56+) lymphocytes and monocytes (CD14+) was significantly increased after HPV immunization (p<0.05 in all cases, Figs. 1C, D, and E, filled bars). Although the expression of ILT2 by CD4+ lymphocytes tended to diminish after immunization, no significant differences were detected, and in the case of CD19+ B cells, no apparent differences in ILT2 expression were detected (Figs. 1G and E). In addition, when PBMCs were stimulated in vitro with the Gardasil vaccine, we found that the percentage of CD8+ cells expressing ILT2 diminished after the administration of the HPV vaccine (p<0.05, Fig. 1A, empty bars). In contrast, the percent of ILT2+ cells into the NK and CD3+CD56+ lymphocyte subsets increased upon in vitro stimulation after immunization (Figs. 1C, and D, empty bars), with no significant differences in the case of B and CD4+ lymphocytes and monocytes (Figs. 1E-G, empty bars).

When the mean fluorescence intensity (MFI) of ILT2 expression was analyzed, we detected a significant increase of this parameter upon HPV immunization in the CD4+, CD8+, CD19+, CD14+, NK and CD3+CD56+ cell subsets (p<0.05 in all cases, Fig 2, filled bars). Similar results were obtained when PBMCs were stimulated in vitro with the Gardasil vaccine (p<0.05, Fig. 2, empty bars).

We also assessed the possible effect of Gardasil immunization on the expression of other immune innate receptors, including the inhibitory receptor NKG2A (which is associated with CD94), and the stimulatory receptors NKG2D, NKp30 (which interacts with viral and endogenous proteins), and NKp46 (which interacts with the hemagglutinin of influenza virus). We found that Gardasil
administration was associated with a significant increase in the percentage of NK cells expressing the four receptors that were tested (p<0.05 in all cases, Figs. 3A-D). Similar results were found in the case of CD3+CD56+ lymphocytes (Figs. 3E, F). These results were also associated with a significant increase in the density (MFI) of NKG2D, NKp30 and NKp46 molecule expression by NK cells (p<0.05 in all cases, Figs. 3G-I). However, CD3+CD56+ cells did not show significant variations in the level of expression of the four receptors studied (data not shown). Finally, it is important to mention that we did not observe significant variations in the proportion of CD3-CD56+ or CD3+CD56+ cells in the three samples obtained during the study.

Functional assays. We then studied the function of ILT2 before and after Gardasil immunization through an assay of inhibition of cell proliferation by using CFSE labeling and flow cytometry analysis. As shown in Fig. 4A and B, a significant reduction in the cell proliferation induced by Gardasil was observed when PBMCs were incubated in the presence of an agonistic anti-ILT2 mAb. In addition, an enhanced inhibitory function of ILT2 after Gardasil administration was detected in both CFSE and DNA content analysis (p<0.05 in both cases, Fig. 4A and B, empty bars, and Fig. 4C).

Additional functional assays of cytokine synthesis showed that the number of IFN-γ producing lymphocytes tended to increase upon Gardasil administration (Fig. 5, black bars). Furthermore, when cells were stimulated in vitro with the Gardasil vaccine, we detected a significant increase in the number of cells synthesizing IFN-γ (Fig. 5, empty bars). Additional experiments indicated that CD56+ lymphocytes were the main source of IFN-γ synthesis in these assays (data not shown). However, when these cells were simultaneously stimulated through ILT2 (with the agonistic HP-F1 mAb plus a cross-linker antibody), no significant inhibition of IFN-γ production was detected (Fig. 5, grey bars).

When the production of IL-10 was analyzed, we detected a significant reduction in the release of this cytokine when cells were incubated in the presence of Gardasil and an agonistic anti-ILT2 mAb (p<0.05, data not shown). However, the
biological consequences of these variations may not be significant due to the small reduction in concentration (approximately 2 pg/ml, data not shown).
Cervical cancer affects approximately 500,000 women each year and almost all cases are associated to HPV infection [4]. The immune response elicited by HPV includes the production of specific antibodies as well as a cell mediated response. However, persistent HPV infection occurs in 10-20% of infected individuals due to a series of immune evasion mechanisms [23]. Although HPV infects basal keratinocytes, high level viral protein expression and viral assembly usually is limited to the upper layers of epithelia avoiding contact with cells of the immune system, such as Langerhans cells. In addition, assembly of HPV virions or self assembly of L1 into VLPs is required for an efficient production of L1-specific IgG1 and IgG2 antibodies [24,28]. Thus, HPV-specific antibodies are not detected in a large proportion of infected individuals. Nevertheless, clearance of HPV is accompanied by antibody production directed against L1 antigen and passive transfer of specific antibodies in animal models has shown to confer immunity against infection [24]. Likewise, the protection against HPV induced by L1 vaccine is associated with production of antibodies specific for this antigen [23]. On the other hand, cell mediated immunity also has a relevant role in the control of HPV infection. Thus, the development of an immune response mediated by CD4+ Th1 lymphocytes has been associated to regression of ano-genital warts [20]. In addition, the increased frequency of cervical cancer in patients with altered CD4+ cells highlights the importance of this cell population in the control of HPV infection [22].

Evasion of the innate immune system is thought to play a key role in the ability of HPV to cause persistent infection. This is reflected in the absence of an inflammatory response to the virus, as well as down regulation of interferon release [12]. In addition, several studies have suggested that evasion of NK cell activity may play a role in the development of cervical cancer [20,7,26,3]. In this regard, Carrington et al. found that the presence of the KIR3DS1 gene is a risk factor for developing cervical cancer [3]. In addition, a reduction in the expression of NKp30, NKp46 and NKG2D by NK cells of women with cervical cancer has been reported.
It has also been shown that HPV E6 and E7 proteins interfere with the binding of IL-18 to its receptor, resulting in a reduction in IFN-γ production by NK cells [12]. Furthermore, it has been detected in different malignant tumors the expression of HLA-G, which interacts with the inhibitory receptors ILT2, ILT4 and KIR 2DL4, and this has been suggested as a mechanism leading to evasion of NK cell activity [21]. In this regard, it has been reported an increased expression of HLA-G in patients with cervical malignancies [29] as well as a reduced synthesis of some activating ligands for NK cell receptors [25]. Altogether, these studies suggest that modulation of the expression of NK receptors and their ligands participate in the immune response to HPV. However, the precise role of different NK cell receptors in this context has not been fully defined. Furthermore, there is little information regarding the response of NK cells to HPV vaccination.

In this study we have detected an increased expression of NKG2A, NKG2D, NKp30 and NKp46 by NK cells, and of ILT2 by monocytes, NK and CD3+CD56+ lymphocytes after HPV vaccination. In addition, an increase in the density of expression (MFI) of ILT2, NKG2D, NKp30 and NKp36 was also observed. ILT2 is a negative regulatory receptor that has been shown to participate in the immunopathogenesis of several autoimmune diseases [14,5]. Furthermore, an increase in the expression of this receptor by NK and T lymphocytes has been shown in association with HCMV infection [8,15]. Although the precise role of ILT2 in this condition has not been fully elucidated, it is very feasible that an increased expression of this receptor may contribute to down-regulate the immune response against HCMV. In this regard, it has been reported that cytotoxic T cells may express ILT2 and that this receptor modulates their lytic activity [13,10]. Thus, our data showing an increased expression and function of ILT2 after Gardasil immunization strongly suggest that this receptor may also have a relevant role in the modulation of the innate and adaptive immune response against HPV. Interestingly, we have observed that the enhanced synthesis of IFN-γ observed in vitro upon Gardasil immunization is not affected by ILT2 engagement, indicating that the regulatory effect of this receptor is not exerted on all immune parameters that are relevant in the response against HPV. In this regard, it has been recently
reported that NK cells exposed to HPV-VLPs show an increased cytotoxic activity and cytokine production (including IFN-γ) [18]. Therefore, it is possible that the enhanced production of IFN-γ observed by us upon HPV immunization could be related to the increased expression of activating receptors by NK cells, and to a lack of a regulatory effect mediated by ILT2 on this immune parameter. In this regard, the possible effect of Gardasil immunization on the cytotoxic activity of NK lymphocytes remains as an interesting point to be addressed.

Interestingly, we have observed that while the proportion of CD8+ lymphocytes that expressed ILT2 decreased after immunization, there was an increase in the density (MFI) of this receptor in these cells. Although the underlying mechanism for this apparent paradoxical effect remains to be determined, our data suggest that in the fraction of CD8+ cells that remain ILT2+ after Gardasil immunization, the enhanced density of this receptor may exert an increased regulatory effect.

The in vitro effect of Gardasil on the expression of ILT2 by NK cells after HPV immunization is of interest. It is feasible that the induction of ILT2 expression by Gardasil in these cells observed by us corresponds to the memory-like phenomenon described in different circumstances for NK lymphocytes [29]. However, it is also possible that this induction is mediated by cytokines released by T cells. Finally, the adjuvant contained in the vaccine (aluminum) might also contribute to the induction of ILT2.

Overall, the profile of NK receptors displayed by NK cells after immunization differs significantly from changes observed in association with persistent HPV infection and cervical cancer [7]. This may reflect differences in the route of antigen exposure, an effect produced by the combination of antigen and adjuvant contained in the vaccine, the absence of the effects produced by HPV-E6 and -E7, or genetic host related factors.

In summary, our observations indicate that HPV immunization is associated with significant changes in the expression and function of immune innate and regulatory receptors, a phenomenon that may contribute to the protective effect of this vaccine.
